

The Geometric Limit of the Swirl-String Mass Functional: Bridging Topological Impedance and Gravitational Time Dilation

Abstract

We present a purely geometric formulation of the mass functional within Swirl-String Theory (SST), demonstrating that the invariant rest mass of topological field configurations can be expressed entirely through spatial length ratios and a canonical medium density. By systematically bridging the Compton wavelength (λ_c), the localized swirl core radius (r_c), and the Planck length (L_p), we derive the electromagnetic fine-structure amplification factor $4/\alpha$ as a strictly geometric shielding gate, defined as $\lambda_c/(\pi r_c)$. This derivation eliminates explicit kinematic velocities and electromagnetic parameters from the baseline mass scale. Furthermore, we demonstrate that the general relativistic Schwarzschild potential for any topological state reduces to a dimensionless impedance factor governed by the fundamental area ratio L_p^2/λ_c . This establishes a first-principles continuity between quantized microscopic defect tension and macroscopic gravitational time dilation without introducing novel mass parameters.

1 Introduction

In standard particle physics, inertial mass is traditionally treated either as an empirical input or as a coupling parameter derived from spontaneous symmetry breaking. Swirl-String Theory (SST) proposes an alternative, purely hydrodynamic framework where particles are modeled as stable, knotted vortex strings within an incompressible, inviscid foliation. In this paradigm, mass is not a fundamental charge but an emergent dynamical property: the topologically trapped, localized kinetic energy of a high-density core condensate.

Previous evaluations of topological mass functionals required the explicit inclusion of characteristic kinematic variables—such as the canonical swirl speed v_ζ —and empirical scaling factors to account for the energy gap between fully shielded, rationally slice configurations (e.g., the electron) and exposed, multi-component composites (e.g., baryons). A persistent theoretical challenge has been isolating the purely geometric dependencies of these invariants to formally decouple the spatial structure of the string from the dynamical wave-speed of the background medium.

This paper establishes the strict geometric limit of the SST mass functional. By utilizing the fundamental closure identity that relates the Compton frequency to the core swirl velocity, we systematically eliminate all free kinematic variables. We establish that the invariant mass of any discrete configuration T is governed strictly by a dimensionless ropelength proxy $L_{\text{tot}}(T)$ and a canonical mass-equivalent density ρ_m .

Crucially, we prove that the inter-sector amplification factor—traditionally associated with the fine-structure constant α —arises not from electromagnetic coupling, but as a purely geometric impedance mismatch between the core radius r_c and the Compton wavelength λ_c .

Finally, we map this geometrically derived mass functional directly into the framework of General Relativity. By substituting the topological mass ratio into the standard Schwarzschild proper time equation, we demonstrate that gravitational time dilation operates as a pure geo-

*the fine-structure constant α —arises not from electromagnetic coupling, but as a purely geometric impedance mismatch between the core radius r_c and the Compton wavelength λ_c .

We define a *core energy density* ρ_E (J/m³) and its mass-equivalent

$$\rho_m := \frac{\rho_E}{c^2} \quad (\text{kg/m}^3). \quad (3)$$

This avoids dimensional ambiguity if one uses “energy density” language in the mass functional.

2.2 Elimination of kinematic variables via the Compton–core identity

From (2), we isolate the velocity ratios:

$$\frac{v_\odot}{c} = \frac{2\pi r_c}{\lambda_c}, \quad \frac{c}{v_\odot} = \frac{\lambda_c}{2\pi r_c}. \quad (4)$$

2.3 Geometric baseline mass scale

Assume a localized kinetic-energy density of the form

$$u = \frac{1}{2}\rho_m v_\odot^2 = \frac{1}{2}\frac{\rho_E}{c^2}v_\odot^2, \quad (5)$$

and a geometric core volume

$$V := \pi r_c^3 L_{\text{tot}}(T), \quad (6)$$

where $L_{\text{tot}}(T)$ is a dimensionless ropelength-like factor.

Then the inertial mass scale defined by energy equivalence is

$$M_0(T) := \frac{uV}{c^2} = \frac{1}{2}\rho_m \left(\frac{v_\odot}{c}\right)^2 \pi r_c^3 L_{\text{tot}}(T). \quad (7)$$

Substituting (4) into (7) gives the *pure geometric* form:

$$M_0(T) = 2\pi^3 \rho_m \frac{r_c^5}{\lambda_c^2} L_{\text{tot}}(T). \quad (8)$$

Dimensional check: ρ_m (kg/m³) times r_c^5/λ_c^2 (m³) yields kg. *No free kinematic variable remains.*

2.4 Substitution of the shielding gate

From the previously established geometric identity for the sector gate:

$$\frac{4}{\alpha} = \frac{2c}{v_\odot} = \frac{\lambda_c}{\pi r_c}, \quad (9)$$

we define the exposure gate $G(T) \in \{0,1\}$ and a dimensionless topology kernel $\mathcal{K}(T)$. The canonical mass functional becomes:

$$M(T) = \left(\frac{\lambda_c}{\pi r_c}\right)^{G(T)} \mathcal{K}(T) \left(2\pi^3 \rho_m \frac{r_c^5}{\lambda_c^2} L_{\text{tot}}(T)\right). \quad (10)$$

This form contains no explicit fine-structure constant α and no explicit swirl velocity $v_\odot$.

2.5 Numerical gate validation (dimensionless)

Using canonical lengths r_c and λ_c :

$$\frac{\lambda_c}{\pi r_c} \approx 5.48144 \times 10^2, \quad (11)$$

matching $4/\alpha$ at rounding precision.

3 Gravity as Pure Geometric Impedance in SST

3.1 Geometric reduction of the GR coupling term

The General Relativistic (Schwarzschild) proper-time factor may be written in terms of the dimensionless potential:

$$\Phi(T; r) := \frac{2GM(T)}{rc^2}. \quad (12)$$

Using the standard definitions $L_p^2 = \hbar G/c^3$ and $\lambda_c = 2\pi\hbar/(M_e c)$, the electron gravitational radius:

$$r_s(e) := \frac{2GM_e}{c^2} \quad (13)$$

reduces identically to the purely geometric form:

$$r_s(e) = 4\pi \frac{L_p^2}{\lambda_c}. \quad (14)$$

Thus, at the electron scale, the GR “source strength” GM_e/c^2 is equivalently a ratio of the Planck area to the Compton boundary.

3.2 SST topological mass ratio

Define the dimensionless SST mass ratio relative to the electron:

$$\tilde{M}(T) := \frac{M(T)}{M_e} = \left(\frac{\lambda_c}{\pi r_c} \right)^{G(T)} \mathcal{K}(T) \tilde{L}_{\text{tot}}(T), \quad (15)$$

where $G(T) \in \{0, 1\}$ is the exposure (shielding) gate, $\mathcal{K}(T)$ is the topology kernel, and $\tilde{L}_{\text{tot}}(T)$ is the relative ropelength factor.

3.3 GR time dilation with SST substitution

For a knot state T , the GR potential term becomes:

$$\Phi(T; r) = \frac{r_s(e)}{r} \tilde{M}(T) = \frac{4\pi L_p^2}{r\lambda_c} \left(\frac{\lambda_c}{\pi r_c} \right)^{G(T)} \mathcal{K}(T) \tilde{L}_{\text{tot}}(T). \quad (16)$$

Substituting this into the proper-time factor yields:

$$t_{\text{adj}} = \Delta t \sqrt{1 - \Phi(T; r) - \frac{v_{\odot}^2}{c^2} e^{-r/r_c} - \frac{(\omega r_c)^2}{c^2} e^{-r/r_c}}. \quad (17)$$

Interpretation (precise claim). The GR structure is retained; SST enters only through $\tilde{M}(T)$. In this combined model, the gravitational time-dilation term can be written as a product of (i) a universal length-ratio prefactor $4\pi L_p^2/(r\lambda_c)$ and (ii) a purely dimensionless topological impedance factor $(\lambda_c/(\pi r_c))^{G(T)} \mathcal{K}(T) \tilde{L}_{\text{tot}}(T)$. No additional mass parameters are introduced beyond the electron normalization. The explicit symbols G and M no longer appear separately: the potential is controlled by geometric ratios. Thus, the apparent cancellation is a reparameterization resulting from positing $M(T)$ geometrically.

4 Status, Assumptions, and Falsifiers

Assumptions: (i) energy density model follows $u = \frac{1}{2}\rho_m v_\odot^2$; (ii) geometric core volume follows $V = \pi r_c^3 L_{\text{tot}}$; (iii) closure identity maps the kinematic foliation parameters to the Compton scale exactly; (iv) the exposure gate is discrete and binary $G(T) \in \{0, 1\}$.

Falsifiers: Any empirical inconsistency in the core identity network (e.g., measuring independent drifts in λ_c , r_c , or $v_\odot$) breaks the geometric gate derivation. Furthermore, any failure of the master equation to accurately predict hadronic-to-leptonic sector ratios when L_{tot} and $\mathcal{K}$ are fixed invalidates the physical interpretation of $G(T)$ as an impedance coupling.
